Level Shifting Hot Swappable 2-Wire Bus Buffer with Enable

FEATURES

- **Bidirectional Buffer* for SDA and SCL Lines Increases Fanout**
- **Prevents SDA and SCL Corruption During Live Board Insertion and Removal from Backplane**
- **Logic Threshold ENABLE Input**
- Isolates Input SDA and SCL Lines from Output
- Compatible with I²C™, I²C Fast Mode and SMBus Standards (Up to 400kHz Operation)
- 1V Precharge on all SDA and SCL Lines
- Supports Clock Stretching, Arbitration and Synchronization
- 5V to 3.3V Level Translation
- High Impedance SDA, SCL Pins for $V_{CC} = 0V$, $V_{CC2} = 0V$
- Small 8-Pin DFN and MSOP Packages

APPLICATIONS

- Hot Board Insertion
- Servers
- Capacitance Buffer/Bus Extender
- Desktop Computer

DESCRIPTION

The LTC®4300A-3 hot swappable 2-wire bus buffer allows I/O card insertion into a live backplane without corruption of the data and clock busses. When the connection is made, the LTC4300A-3 provides bidirectional buffering, keeping the backplane and card capacitances isolated. Rise-time accelerator circuitry allows the use of weaker DC pull-up currents while still meeting rise-time requirements. During insertion, the SDA and SCL lines are precharged to 1V to minimize bus disturbances.

The LTC4300A-3 provides level translation between 3.3V and 5V supplies. The backplane and card can both be powered with supplies ranging from 2.7V to 5.5V. The LTC4300A-3 also incorporates a CMOS threshold ENABLE pin which forces the part into a low current mode and isolates the card from the backplane. When driven to V_{CC}, the ENABLE pin sets normal operation.

The LTC4300A-3 is available in the MSOP and 3mm × 3mm DFN packages.

PIN FUNCTIONS

V_{CC2} **(Pin 1):** Card Supply Voltage. This is the supply voltage for the devices on the card I^2C busses. Connect pull-up resistors from SDAOUT and SCLOUT to this pin. Place a bypass capacitor of at least $0.01\mu F$ close to this pin for best results.

SCLOUT (Pin 2): Serial Clock Output. Connect this pin to the SCL bus on the card.

SCLIN (Pin 3): Serial Clock Input. Connect this pin to the SCL bus on the backplane.

GND (Pin 4): Device Ground. Connect this pin to a ground plane for best results.

ENABLE (Pin 5): Digital CMOS Threshold Input. Grounding this pin puts the part in a low current mode. It also disables the rise-time accelerators, disables the bus discharge circuitry, isolates SDAIN from SDOUT and isolates SCLIN from SCLOUT. For active operation, drive this pin to V_{CC}. If this feature is unused, tie to V_{CC}. Since ENABLE is V_{CC} referenced, do not connect to V_{CC2} or pull up to V_{CC2}.

**SDAIN (Pin 6):** Serial Data Input. Connect this pin to the SDA bus on the backplane.

SDAOUT (Pin 7): Serial Data Output. Connect this pin to the SDA bus on the card.

V_{CC} **(Pin 8):** Main Input Power Supply from Backplane. This is the supply voltage for the devices on the backplane I^2C busses. Connect pull-up resistors from SDAIN and SCLIN to this pin. Place a bypass capacitor of at least $0.01\mu F$ close to this pin for best results.

Exposed Pad (Pin 9, DFN Package Only): Exposed Pad may by be left open or connected to device ground.

OPERATION

Start-Up

When the LTC4300A-3 first receives power on its V_{CC} pin, either during power-up or during live insertion, it starts in an undervoltage lockout (UVLO) state, ignoring any activity on the SDA and SCL pins until V_{CC} rises above 2.5V. The part also waits for V_{CC2} to rise above 2V. This ensures that the part does not try to function until it has enough voltage to do so.

During this time, the 1V precharge circuitry is also active and forces 1V through 100k nominal resistors to the SDA and SCL pins. Because the I/O card is being plugged into a live backplane, the voltage on the backplane SDA and SCL busses may be anywhere between 0V and V_{CC}. Precharging the SCL and SDA pins to 1V minimizes the worst-case voltage differential these pins will see at the moment of connection, therefore minimizing the amount of disturbance caused by the I/O card.

Once the LTC4300A-3 comes out of UVLO, it assumes that SDAIN and SCLIN have been inserted into a live system and that SDAOUT and SCLOUT are being powered up at the same time as itself. Therefore, it looks for either a stop bit or bus idle condition on the backplane side to indicate the completion of a data transaction. When either one occurs, the part also verifies that both the SDAOUT and SCLOUT voltages are high. When all of these conditions are met, the input-to-output connection circuitry is activated, joining the SDA and SCL busses on the I/O card with those on the backplane, and the rise time accelerators are enabled.

Connection Circuitry

Once the connection circuitry is activated, the functionality of the SDAIN and SDAOUT pins is identical. A low forced on either pin at any time results in both pin voltages being low. For proper operation, logic low input voltages should be no higher than 0.4V with respect to the ground pin voltage of the LTC4300A-3. SDAIN and SDAOUT enter a logic high state only when all devices on both SDAIN and SDAOUT release high. The same is true for SCLIN and SCLOUT. This important feature ensures that clock stretching, clock synchronization, arbitration and the acknowledge protocol always work, regardless of how the devices in the system are tied to the LTC4300A-3.

Another key feature of the connection circuitry is that it provides bidirectional buffering, keeping the backplane and card capacitances isolated. Because of this isolation, the waveforms on the backplane busses look slightly different than the corresponding card bus waveforms, as described here.

Input to Output Offset Voltage

When a logic low voltage, V_{LOW1}, is driven on any of the LTC4300A-3's data or clock pins, the LTC4300A-3 regulates the voltage on the other side of the part (call it V_{LOW2}) to a slightly higher voltage, as directed by the following equation (typical):

$$V_{LOW2} = V_{LOW1} + 75mV + (V_{CC}/R) \cdot 70 \ [\Omega]$$

where R is the bus pull-up resistance in ohms. For example, if a device is forcing SDAOUT to 10mV where $V_{CC} = 3.3V$ and the pull-up resistor R on SDAIN is 10k, then the voltage on SDAIN = 10mV + 75mV + (3.3/10000) • 70 = 108mV (typical). See the Typical Performance Characteristics section for curves showing the offset voltage as a function of V_{CC} and R.

Propagation Delays

During a rising edge, the rise-time on each side is determined by the combined pull-up current of the LTC4300A-3 boost current and the bus resistor and the equivalent capacitance on the line. If the pull-up currents are the same, a difference in rise-time occurs which is directly proportional to the difference in capacitance between the two sides. This effect is displayed in Figure 1 for $V_{CC} = V_{CC2} = 3.3V$ and a 10k pull-up resistor on each side (50pF on one side and 150pF on the other). Since the output side has less capacitance than the input, it rises faster and the effective propagation delay is negative.

There is a finite propagation delay through the connection circuitry for falling waveforms. Figure 2 shows the falling edge waveforms for the same V_{CC}, pull-up resistors and equivalent capacitance conditions as used in Figure 1. An external NMOS device pulls down the voltage on the side with 150pF capacitance; the LTC4300A-3 pulls down the voltage on the opposite side, with a delay of 55ns. This delay is always positive and is a function of supply voltage,
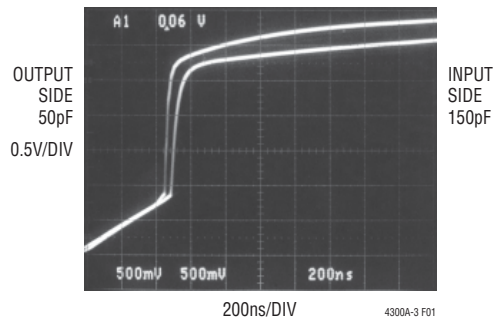

OPERATION

Figure 1. Input–Output Connection Low to High Transition

Figure 2. Input–Output Connection High to Low Transition

temperature and the pull-up resistors and equivalent bus capacitances on both sides of the bus. The Typical Performance Characteristics section shows t_{PHL} as a function of temperature and voltage for 10k pull-up resistors and 100pF equivalent capacitance on both sides of the part. By comparison with Figure 2, the $V_{CC} = V_{CC2} = 3.3V$ curve shows that increasing the capacitance from 50pF to 100pF results in a propagation delay increase from 55ns to 75ns. Larger output capacitances translate to longer delays (up to 150ns). Users must quantify the difference in propagation times for a rising edge versus a falling edge in their systems and adjust setup and hold times accordingly.

Rise-Time Accelerators

Once connection has been established, rise-time accelerator circuits on all four SDA and SCL pins are activated. These allow the user to choose weaker DC pull-up currents on the bus, reducing power consumption while still meeting system rise-time requirements. During positive bus transitions, the LTC4300A-3 switches in 2mA (typical) of current to quickly slew the SDA and SCL lines once their DC voltages exceed 0.6V. Using a general rule of 20pF of capacitance for every device on the bus (10pF for the device and 10pF for interconnect), choose a pull-up current so that the bus will rise on its own at a rate of at least 1.25V/μs to guarantee activation of the accelerators.
For example, assume an SMBus system with V_{CC} = 3V, a 10k pull-up resistor and equivalent bus capacitance of 200pF. The rise-time of an SMBus system is calculated from ($V_{IL(MAX)}$ – 0.15V) to ($V_{IH(MIN)}$ + 0.15V), or 0.65V to 2.25V. It takes an RC circuit 0.92 time constants to traverse this voltage for a 3V supply; in this case, 0.92 • (10k • 200pF) = 1.84μs. Thus, the system exceeds the maximum allowed rise-time of 1μs by 84%. However, using the rise-time accelerators, which are activated at a DC threshold of below 0.65V, the worst-case rise-time is: (2.25V – 0.65V) • 200pF/1mA = 320ns, which meets the 1μs rise-time requirement.

ENABLE Low Current Disable

Grounding the ENABLE pin disconnects the backplane side from the card side, disables the rise-time accelerators, disables the bus precharge circuitry and puts the part in a near-zero current state. When the pin voltage is driven all the way to V_{CC}, the part waits for data transactions on both the backplane and card sides to be complete (as described in the Start-Up section) before reconnecting the two sides.

APPLICATIONS INFORMATION

Resistor Pull-Up Value Selection

The system pull-up resistors must be strong enough to provide a positive slew rate of 1.25V/µs on the SDA and SCL pins, in order to activate the boost pull-up currents during rising edges. Choose maximum resistor value R using the formula:

$$R \leq (V_{CC(MIN)} - 0.6)(800,000)/C$$

where R is the pull-up resistor value in ohms, $V_{CC(MIN)}$ is the minimum V_{CC} voltage and C is the equivalent bus capacitance in picofarads (pF).

In addition, regardless of the bus capacitance, always choose R ≤ 16k for V_{CC} = 5.5V maximum, R ≤ 24k for V_{CC} = 3.6V maximum. The start-up circuitry requires logic high voltages on SDAOUT and SCLOUT to connect the backplane to the card, and these pull-up values are needed to overcome the precharge voltage.

Live Insertion and Capacitance Buffering Application

Figures 3 and 4 illustrate the usage of the LTC4300A-3 in applications that take advantage of both its Hot Swap controlling and capacitance buffering features. In all of these applications, note that if the I/O cards were plugged directly into the backplane, all of the backplane and card capacitances would add directly together, making rise- and fall-time requirements difficult to meet. Placing a LTC4300A-3 on the edge of each card, however, isolates the card capacitance from the backplane. For a given I/O card, the LTC4300A-3 drives the capacitance of everything on the card and the backplane must drive only the capacitance of the LTC4300A-3, which is less than 10pF.

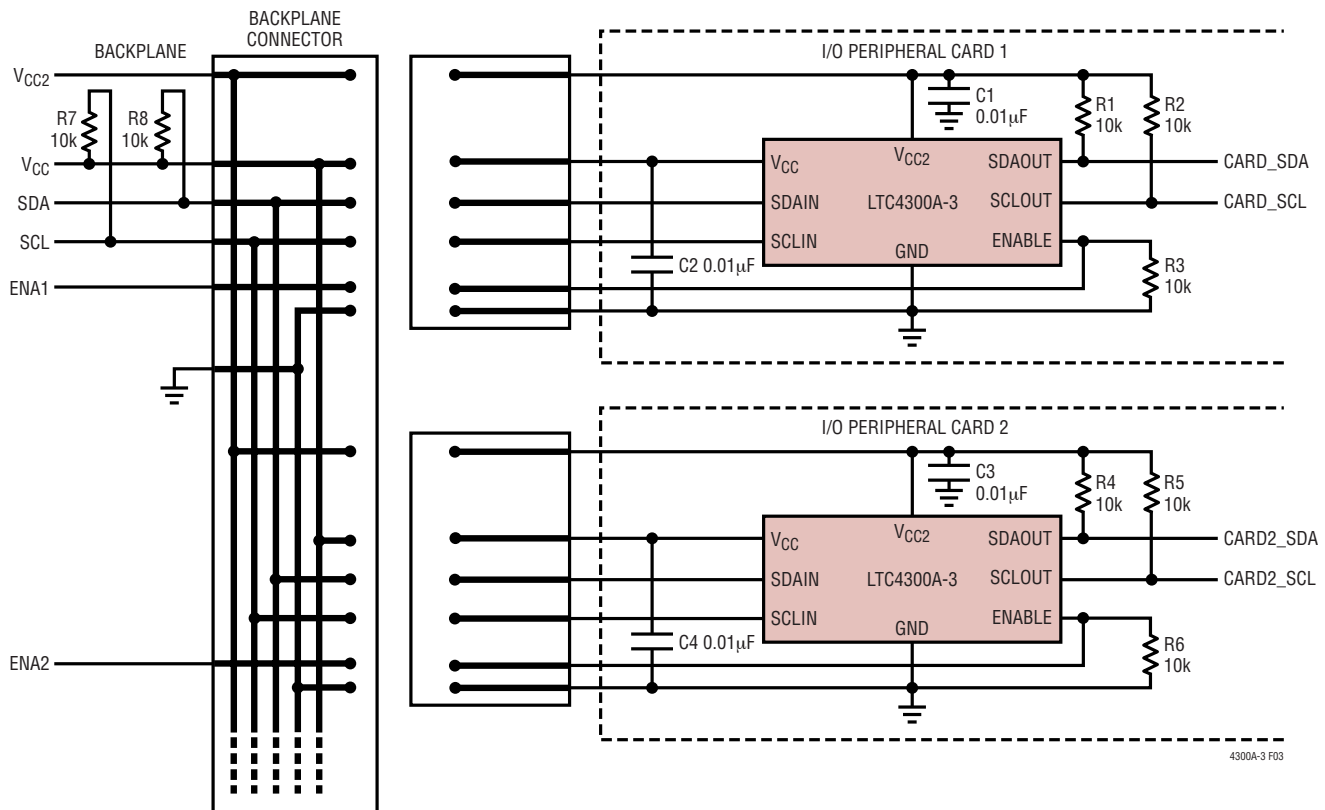

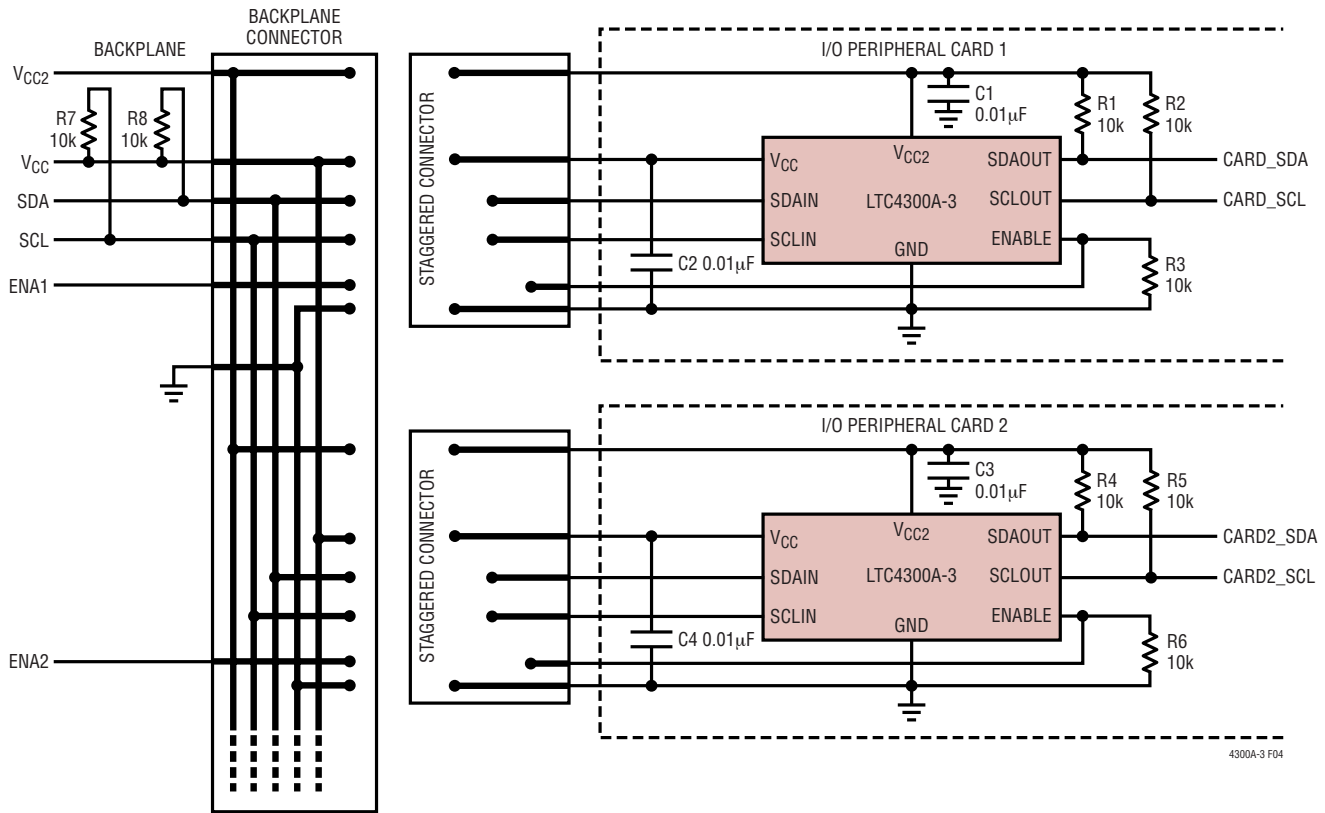

**Figure 3. The LTC4300A-3 in a PCI Application Where All the Pins Have the Same Length.
ENABLE Should be Held Low Until All Transients Associated with the Live Insertion Have Settled**

APPLICATIONS INFORMATION

Figure 4. The LTC4300A-3 in a Custom Application. Making ENABLE the Shortest Pin Ensures that V$_{CC}$ and V$_{CC2}$ Connect Before ENABLE is Allowed to Go High, Connecting the Card to the Backplane

## 5V to 3.3V Level Translator and Power Supply Redundancy

Systems requiring different supply voltages for the backplane side and the card side can use the LTC4300A-3, as shown in Figure 5. The pull-up resistors on the card side connect from SDAOUT to SCLOUT to V$_{CC2}$, and those on the backplane side connect from SDAIN and SCLIN to V$_{CC}$. The LTC4300A-3 functions for voltages ranging from 2.7V to 5.5V on both V$_{CC}$ and V$_{CC2}$. There is no constraint on the voltage magnitudes of V$_{CC}$ and V$_{CC2}$ with respect to each other.

This application also provides power supply redundancy. If the V$_{CC2}$ voltage falls below its UVLO threshold, the LTC4300A-3 disconnects the backplane from the card, so that the backplane can continue to function. If the V$_{CC}$ voltage falls below its UVLO threshold and the V$_{CC2}$ voltage remains active, hold ENABLE at ground to ensure proper operation.
