

Latchable Negative Floating Hot Swap Power Manager

FEATURES

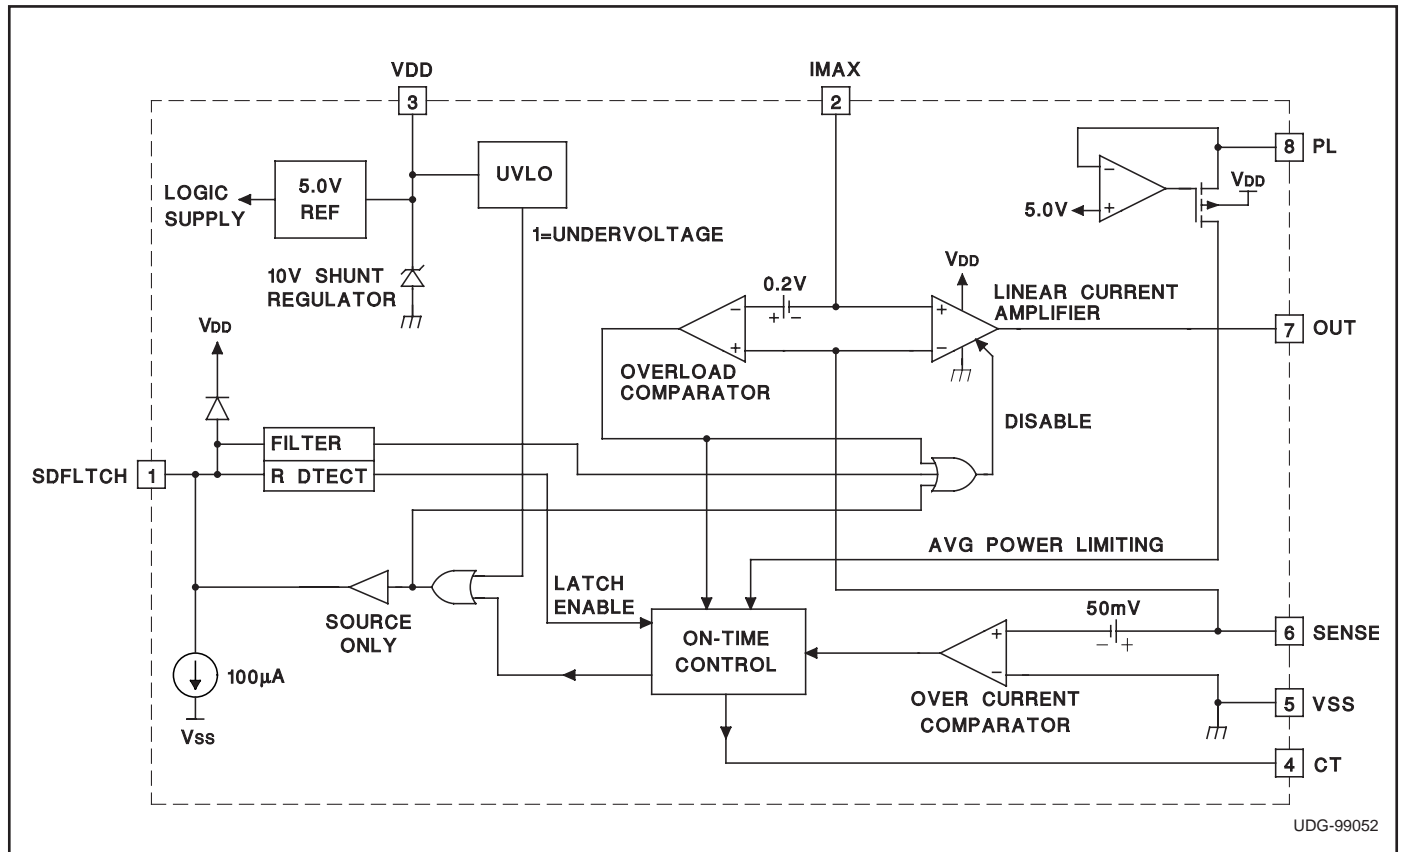

- Precision Fault Threshold
- Programmable:
Average Power Limiting, Linear Current Control, Overcurrent Limit and Fault Time
- Fault Output Indication Signal
- Automatic Retry Mode or Latched Operation Mode
- Shutdown Control
- Undervoltage Lockout
- 250 μ s Glitch Filter on the SDFLTCH pin
- 8-Pin DIL and SOIC

DESCRIPTION

The UCC3921 family of negative floating hot swap power managers provides complete power management, hot swap, and fault handling capability. The IC is referenced to the negative input voltage and is powered through an external resistor connected to ground, which is essentially a current drive as opposed to the traditional voltage drive. The onboard 10V shunt regulator protects the IC from excess voltage and serves as a reference for programming the maximum allowable output sourcing current during a fault. All control and housekeeping functions are integrated and externally programmable. These include the fault current level, maximum output sourcing current, maximum fault time, selection of Retry or Latched mode, soft start time, and average power limiting. In the event of a constant fault, the internal timer will limit the on time from less than 0.1% to a maximum of 3% duty cycle. The duty cycle modulation depends on the current into PL, which is a function of the voltage across the FET, thus limiting average power dissipation in the FET. The fault level is fixed at 50mV across the current sense amplifier to minimize total

(continued)

BLOCK DIAGRAM

DESCRIPTION (continued)

dropout. The fault current level is set with an external current sense resistor, while the maximum allowable sourcing current is programmed with a voltage divider from VDD to generate a fixed voltage on IMAX. The current level, when the output acts as a current source, is equal to V_{IMAX}/R_{SENSE} . If desired, a controlled current start up can be programmed with a capacitor on IMAX.

When the output current is below the fault level, the output device is switched on. When the output current exceeds the fault level, but is less than the maximum sourcing level programmed by IMAX, the output remains switched on, and the fault timer starts charging CT. Once

CT charges to 2.5V, the output device is turned off and performs a retry some time later (provided that the selected mode of operation is Automatic Retry Mode). When the output current reaches the maximum sourcing current level, the output acts as a current source, limiting the output current to the set value defined by IMAX.

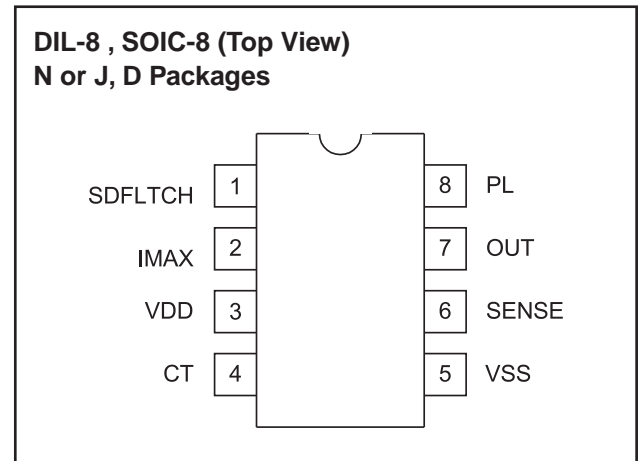

Other features of the UCC3921 include undervoltage lockout, 8-pin Small Outline (SOIC) and Dual-In-Line (DIL) packages, and a Latched Operation Mode option, in which the output is latched off once CT charges to 2.5V and stays off until either SDFLTCH is toggled (for greater than 1ms) or the IC is powered down and then back up.

ABSOLUTE MAXIMUM RATINGS

I _{VDD}	50mA
SDFLTCH Current	10mA
PL Current	10mA
IMAX Input Voltage	VDD
Storage Temperature	-65°C to +150°C
Junction Temperature	-55°C to +150°C
Lead Temperature (Soldering, 10 sec.)	+300°C

All voltages are with respect to V_{SS} (the most negative voltage). Currents are positive into, negative out of the specified terminal. Consult Packaging Section of Databook for thermal limitations and considerations of packages.

Note 1: Guaranteed by design. Not 100% tested in production.

PIN DESCRIPTIONS

CT: A capacitor is connected to this pin in order to set the fault time. The fault time must be longer than the time to charge external load capacitance. The fault time is defined as:

$$T_{FAULT} = \frac{2 \cdot C_T}{I_{CH}}$$

where $I_{CH} = 36\mu\text{A} + I_{PL}$, and I_{PL} is the current into the power limit pin. Once the maximum fault time is reached the output will shutdown for a time given by:

$$T_{SD} = 2 \cdot 10^6 \cdot C_T$$

IMAX: This pin programs the maximum allowable sourcing current. Since VDD is a regulated voltage, a voltage divider can be derived from VDD to generate the program level for IMAX. The current level at which the output appears as a current source is equal to the

voltage on IMAX over the current sense resistor. If desired, a controlled current start up can be programmed with a capacitor on IMAX, and a programmed start delay can be achieved by driving the shutdown with an open collector/drain device into an RC network.

OUT: This pin provides gate output drive to the MOSFET pass element.

PL: This feature ensures that the average MOSFET power dissipation is controlled. A resistor is connected from this pin to the drain of the NMOS pass element. When the voltage across the NMOS exceeds 5V, current will flow into the PL pin which adds to the fault timer charge current, reducing the duty cycle from the 3% level. When $I_{PL} \gg 36\mu\text{A}$, then the average MOSFET power dissipation is given by:

$$P_{MOSFET\text{avg}} = IMAX \cdot 1 \cdot 10^{-6} \cdot R_{PL}$$

PIN DESCRIPTIONS (continued)

SENSE: Input voltage from the current sense resistor. When there is greater than 50mV across this pin with respect to VSS, then a fault is sensed, and C_T starts to charge.

SDFLTCH: This pin provides fault output indication, shutdown control, and operating mode selection. Interface into and out of this pin is usually performed through level shift transistors. When open, and under a non-fault condition, this pin pulls to a low state with respect to VSS. When a fault is detected by the fault timer, or undervoltage lockout, this pin will drive to a high state with respect to VSS, indicating the NMOS pass element is OFF. When $> 250\mu A$ is sourced into this pin for $> 1ms$, it drives high causing the output to disable the NMOS pass device.

If an $5k < R_{LATCH} < 250k\Omega$ resistor is placed from this pin to VSS, then the latched operating mode will be invoked. Upon the occurrence of a fault, under the latched mode of operation, once the C_T capacitor charges up to 2.5V the NMOS pass element latches off. A retry will not periodically occur. To reset the latched off device, either SDFLTCH is toggled high for a duration greater than 1ms or the IC is powered down and then up.

VDD: Current driven with a resistor to a voltage approximately 10V more positive than VSS. Typically a resistor is connected to ground. The 10V shunt regulator clamps VDD approximately 10V above VSS, and is also used as an output reference to program the maximum allowable sourcing current.

VSS: Ground reference for the IC and the most negative voltage available.

APPLICATION INFORMATION

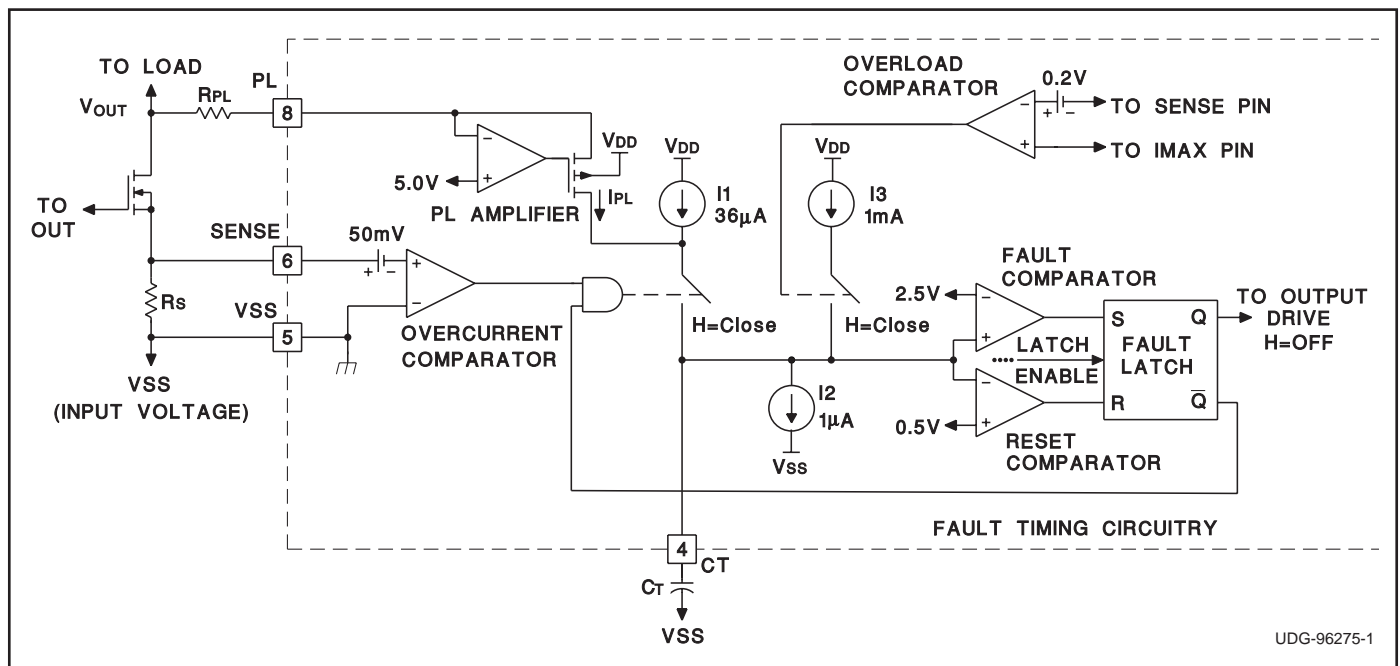

Figure 1. Fault Timing Circuitry for the UCC3921, Including Power Limit Overload

APPLICATION INFORMATION (continued)

Figure 1 shows the detailed circuitry for the fault timing function of the UCC3921. For the time being, we will discuss a typical fault mode, therefore, the overload comparator, and current source I3 does not work into the operation. Once the voltage across the current sense resistor, R_s , exceeds 50mV, a fault has occurred. This causes the timing capacitor to charge with a combination of 36 μ A plus the current from the power limiting amplifier. The PL amplifier is designed to only source current into the CT pin and to begin sourcing current once the voltage across the output FET exceeds 5V. The current I_{PL}

is related to the voltage across the FET with the following expression:

$$I_{PL} = \frac{V_{FET} - 5V}{R_{PL}}$$

where V_{FET} is the voltage across the NMOS pass device. Later it will be shown how this feature will limit average power dissipation in the pass device. Note that under a condition where the output current is more than the fault level, but less than the max level, $V_{OUT} \approx V_{SS}$ (input voltage), $I_{PL} = 0$, the CT charging current is 36 μ A.

Figure 2. Retry Operation Mode

t₀: Safe condition. Output current is nominal, output voltage is at the negative rail, V_{SS} .

t₁: Fault control reached. Output current rises above the programmed fault value, CT begins to charge at ~36 μ A.

t₂: Maximum current reached. Output current reaches the programmed maximum level and becomes a constant current with value I_{MAX} .

t₃: Fault occurs. CT has charged to 2.5V, fault output goes high, the FET turns off allowing no output current to flow, V_{OUT} floats up to ground.

t₄: Retry. CT has discharged to 0.5V, but fault current is still exceeded, CT begins charging again, FET is on, V_{OUT} pulled down towards V_{SS} .

t₅ = t₃: Illustrates 3% duty cycle.

t₆ = t₄: Retry. CT has discharged to 0.5V, but fault is still exceeded, CT begins charging again, FET is on, V_{OUT} pulled down towards V_{SS} .

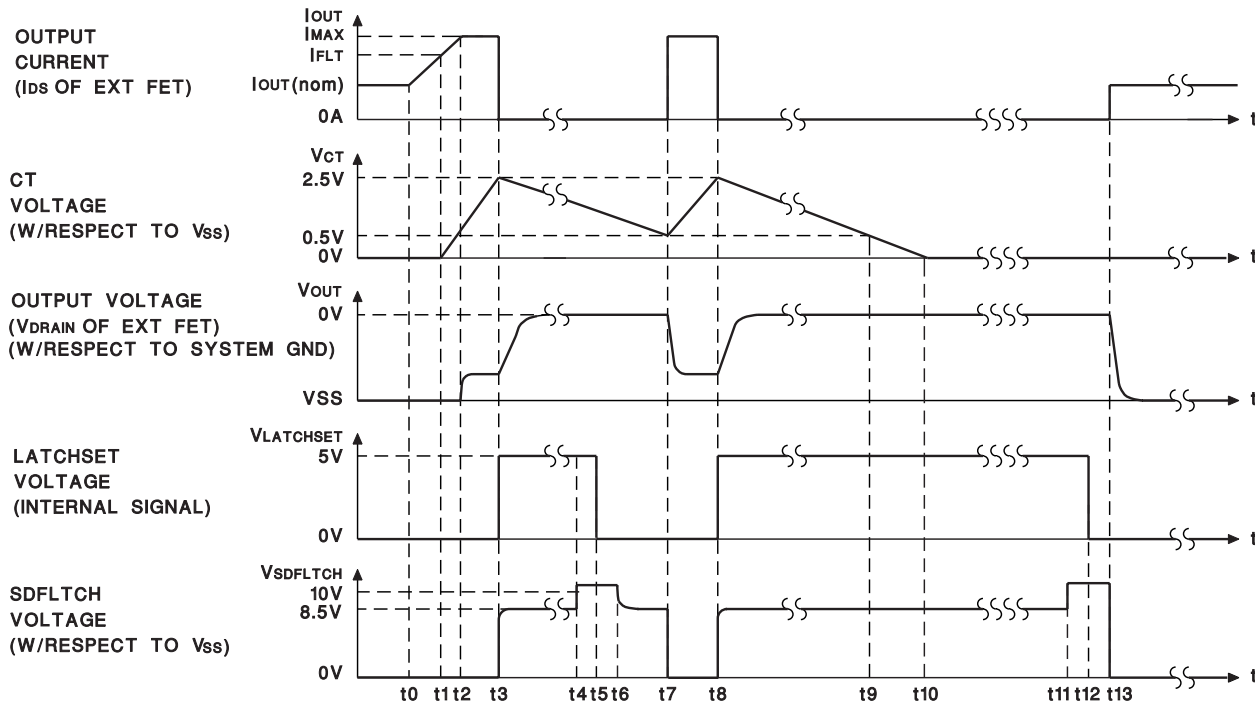

t₇: Output short circuit. If V_{OUT} is short circuited to ground, CT charges at a higher rate depending upon the values for V_{SS} and R_{PL} .

t₈: Fault occurs. Output is still short circuited, but the occurrence of a fault turns the FET off so no current is conducted.

t₉ = t₄: Output short circuit released, still in fault mode.

t₁₀ = t₀: Fault released, safe condition. Return to normal operation of the hot swap power manager.

APPLICATION INFORMATION (cont.)

UDG-96277

t₀: Safe condition. Output current is nominal, output voltage is at the negative rail, V_{SS}.

t₁: Fault control reached. Output current rises above the programmed fault value, CT begins to charge at ~36μA.

t₂: Maximum current reached. Output current reaches the programmed maximum level and becomes a constant current with value I_{MAX}.

t₃: Fault occurs. CT has charged to 2.5V, fault output goes high as indicated by the SDFLTCH voltage. The FET turns off allowing no output current to flow, V_{OUT} floats up to ground, and since there is an 82kΩ resistor from the SDFLTCH pin to V_{SS}, the internal latchset signal goes high.

t₄: Since the user does not want the chip to LATCH off during this cycle, he toggles SDFLTCH high for greater than 1ms {t₆ - t₄ > 1ms}.

t₅: The latchset signal is reset.

t₆: Forcing of SDFLTCH is released after having been applied for > 1ms.

t₇: Retry (since the latchset signal has been reset to its' low state) - CT has discharged to 0.5V, but fault current

is still exceeded, CT begins charging again, FET is on, V_{OUT} pulled down towards V_{SS}.

t₈ = t₃: Fault occurs. CT has charged to 2.5V, fault output goes high as indicated by the SDFLTCH voltage, the FET turns off allowing no output current to flow, V_{OUT} floats up to ground, and since there is an 82kΩ resistor from SDFLTCH to V_{SS}, the internal latchset signal goes high.

t₉: Output is latched off. Even though CT has discharged to 0.5V, there will not be a retry since the latchset signal was allowed to remain high.

t₁₀: Output remains latched off. CT has discharged all the way to 0V.

t₁₁: The output has been latched off for quite some time. The user now wishes to reset the latched off output, thus toggling SDFLTCH high for greater than 1ms {t₁₃ - t₁₁}.

t₁₂ = t₅: The latchset signal is reset.

t₁₃: Forcing of SDFLTCH is released after having been applied for > 1ms. The fault had also been released during the time the output was latched off, safe condition, return to normal operation of the hot swap power manager.

Figure 3. Latched Operation Mode: R_{LATCH} = 82k

APPLICATION INFORMATION (continued)

During a fault, CT will charge at a rate determined by the internal charging current and the external timing capacitor. Once CT charges to 2.5V, the fault comparator switches and sets the fault latch. Setting of the fault latch causes both the output to switch off and the charging switch to open. CT must now discharge with the 1μA current source, I2, until 0.5V is reached. Once the voltage at CT reaches 0.5V, the fault latch resets, which re-enables the output and allows the fault circuitry to regain control of the charging switch. If a fault is still present, the fault comparator will close the charging switch causing the cycle to repeat. Under a constant fault, the duty cycle is given by:

$$\text{Duty Cycle} = \frac{1\mu\text{A}}{I_{PL} + 36\mu\text{A}}$$

Average power dissipation in the pass element is given by:

$$P_{FET_{AVG}} = V_{FET} \cdot I_{MAX} \cdot \frac{1\mu\text{A}}{I_{PL} + 36\mu\text{A}}$$

Where $V_{FET} \gg 5V$ I_{PL} can be approximated as:

$$\frac{V_{FET}}{R_{PL}}$$

and where $I_{PL} \gg 36\mu\text{A}$, the duty cycle can be approximated as :

$$\frac{1\mu\text{A} \cdot R_{PL}}{V_{FET}}$$

Therefore, the maximum average power dissipation in the MOSFET can be approximated by:

$$\begin{aligned} P_{FET_{AVG}} &= V_{FET} \cdot I_{MAX} \cdot \frac{1\mu\text{A} \cdot R_{PL}}{V_{FET}} \\ &= I_{MAX} \cdot 1\mu\text{A} \cdot R_{PL} \end{aligned}$$

Notice that in the approximation, V_{FET} cancels, thereby limiting the average power dissipation in the NMOS pass element.

Overload Comparator

The linear amplifier in the UCC3921 ensures that the output NMOS does not pass more than I_{MAX} (which is V_{IMAX}/R_{SENSE}). In the event the output current exceeds the programmed I_{MAX} by $0.2V/R_{SENSE}$, which can only occur if the output FET is not responding to a command from the IC, CT will begin charging with I3, 1mA, and continue to charge to approximately 8V. This allows a constant fault to show up on the SDFLTCH pin, and also since the voltage on CT will continue charging past 2.5V in an overload fault mode, it can be used for detection of

output FET failure or to build redundancy into the system.

Determining External Component Values

To set R_{VDD} (see Fig. 4) the following must be achieved:

$$\frac{V_{IN \text{ min}}}{R_{VDD}} > \frac{10V}{R1 + R2} + 2mA$$

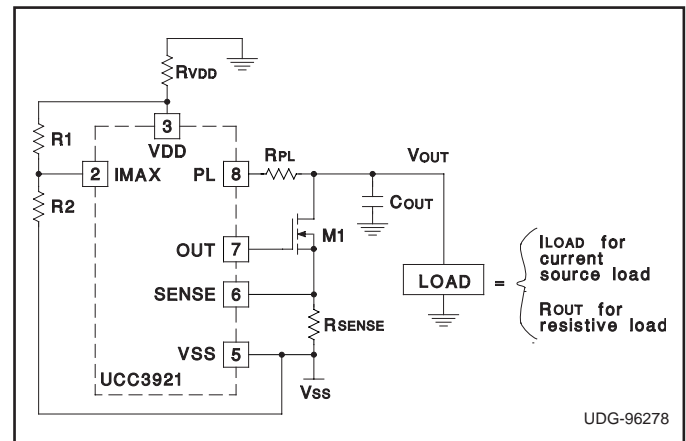

Figure 4.

In order to estimate the minimum timing capacitor, C_T , several things must be taken into account. For example, given the schematic in Figure 4 as a possible (and at this point, a standard) application, certain external component values must be known in order to estimate C_{TMIN} . Now, given the values of C_{OUT} , Load, R_{SENSE} , V_{SS} , and the resistors determining the voltage on the IMAX pin, the user can calculate the approximate startup time of the node V_{OUT} . This startup time must be faster than the time it takes for C_T to charge to 2.5V (relative to V_{SS}), and is the basis for estimating the minimum value of C_T . In order to determine the value of the sense resistor, R_{SENSE} , assuming the user has determined the fault current, R_{SENSE} can be calculated by:

$$R_{SENSE} = \frac{50mV}{I_{FAULT}}$$

Next, the variable I_{MAX} must be calculated. I_{MAX} is the maximum current that the UCC3921 will allow through the transistor, M1, and it can be shown that during startup with an output capacitor the power MOSFET, M1, can be modeled as a constant current source of value I_{MAX} where

$$I_{MAX} = \frac{V_{IMAX}}{R_{SENSE}} \text{ where } V_{IMAX} = \text{voltage on pin IMAX.}$$

Given this information, calculation of the startup time is now possible via the following:

APPLICATION INFORMATION (continued)

Current Source Load:

$$T_{START} = \frac{C_{OUT} \cdot |V_{SS}|}{I_{MAX} - I_{LOAD}}$$

Resistive Load:

$$T_{START} = \frac{C_{OUT} \cdot R_{OUT} \cdot \ln\left(\frac{I_{MAX} \cdot R_{OUT}}{I_{MAX} \cdot R_{OUT} - |V_{SS}|}\right)}{5 \cdot R_{PL}}$$

Once T_{START} is calculated, the power limit feature of the UCC3921 must be addressed and component values derived. Assuming the user chooses to limit the maximum

Figure 5. Plot Average Power vs FET Voltage for Increasing Values of R_{PL}

allowable average power that will be associated with the hot swap power manager, the power limiting resistor, R_{PL} , can be easily determined by the following:

$$R_{PL} = \frac{P_{FET\ avg}}{1\mu A \cdot I_{MAX}}$$

defined by $R_{PL\ min} = \frac{|V_{SS}|}{5mA}$ (Refer to Figure 5).

Finally, after computing the aforementioned variables, the minimum timing capacitor can be derived as such:

Current Source Load:

$$C_T\ min = \frac{3 \cdot T_{START} \cdot (72\mu A \cdot R_{PL} + |V_{SS}| - 10V)}{10 \cdot R_{PL}}$$

Resistive Load:

$$C_T\ min = \frac{3 \cdot T_{START} \cdot (36\mu A \cdot R_{PL} + |V_{SS}| - 5V - I_{MAX} \cdot R_{OUT})}{5 \cdot R_{PL}} + \frac{3 \cdot R_{OUT} \cdot |V_{SS}| \cdot C_{OUT}}{5 \cdot R_{PL}}$$

Level Shift Circuitry to Interface with SDFLTCH

Some type of circuit is needed to interface with the UCC3921 via SDFLTCH, such as opto-couplers or level shift circuitry. Figure 6 depicts one implementation of level shift circuitry that could be used, showing component values selected for a typical -48V telecommunication application. There are three communication conditions which could occur; two of which are Hot Swap Power Manager (HSPM) state output indications, and the third being an External Shutdown.

- 1) When open, and under a non-fault condition, SDFLTCH is pulled to a low state. In Figure 6, the N-channel level shift transistor is off, and the FAULT OUT signal is pulled to LOCAL VDD through R3. This indicates that the HSPM is not faulted.
- 2) When a fault is detected by the fault timer or under-voltage lockout, this pin will drive to a high state, indicating that the external power FET is off. In Figure 6, the N-channel level shift transistor will conduct, and the FAULT OUT signal will be pulled to a Schottky Diode voltage drop below LOCAL GND. This indicates that the HSPM is faulted. The Schottky Diode is necessary to ensure that the FAULT OUT signal does not traverse too far below LOCAL GND, making fault detection difficult.

Figure 6. Possible Level Shift Circuitry to Interface to the UCC3921, showing component values selected for a typical telecom application.

APPLICATION INFORMATION (continued)

If a $5k < R_{LATCH} < 250k\Omega$ resistor is tied between SDFLTCH & VSS, as optionally shown in Figure 6, then the latched operating mode (described earlier) will be invoked upon the occurrence of a fault.

- 3) To externally shutdown the HSPM, the SHUTDOWN signal (typically held at LOCAL VDD) must be pulled to LOCAL GND. Assuming SHUTDOWN is tied to LOCAL GND, the P-channel level shift transistor will conduct, driving SDFLTCH high (to roughly VDD plus a diode). By sourcing $> 250\mu A$ into SDFLTCH for $> 1ms$ the output to the external power FET will be disabled. The current sourced into SDFLTCH must be

limited to 10mA or less: $ISDFLTCHMAX < 10mA$.

SAFETY RECOMMENDATIONS

Although the UCC3921 is designed to provide system protection for all fault conditions, all integrated circuits can ultimately fail short. For this reason, if the UCC3921 is intended for use in safety critical applications where UL[®] or some other safety rating is required, a redundant safety device such as a fuse should be placed in series with the external power FET. The UCC3921 will prevent the fuse from blowing for virtually all fault conditions, increasing system reliability and reducing maintenance cost, in addition to providing the hot swap benefits of the device.

⁽¹⁾ The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSOLETE: TI has discontinued the production of the device.

⁽²⁾ Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check <http://www.ti.com/productcontent> for the latest availability information and additional product content details.

TBD: The Pb-Free/Green conversion plan has not been defined.

Pb-Free (RoHS): TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.

Pb-Free (RoHS Exempt): This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.

Green (RoHS & no Sb/Br): TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

⁽³⁾ MSL, Peak Temp. -- The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

P (R-PDIP-T8)

PLASTIC DUAL-IN-LINE PACKAGE

- NOTES:
- A. All linear dimensions are in inches (millimeters).
 - B. This drawing is subject to change without notice.
 - C. Falls within JEDEC MS-001 variation BA.

D (R-PDSO-G8)

PLASTIC SMALL OUTLINE

- NOTES:
- A. All linear dimensions are in inches (millimeters).
 - B. This drawing is subject to change without notice.
 - Body length does not include mold flash, protrusions, or gate burrs. Mold flash, protrusions, or gate burrs shall not exceed 0.006 (0,15) each side.
 - Body width does not include interlead flash. Interlead flash shall not exceed 0.017 (0,43) each side.
 - E. Reference JEDEC MS-012 variation AA.

D (R-PDSO-G8)

PLASTIC SMALL OUTLINE

- NOTES:
- All linear dimensions are in millimeters.
 - This drawing is subject to change without notice.
 - Publication IPC-7351 is recommended for alternate designs.
 - Laser cutting apertures with trapezoidal walls and also rounding corners will offer better paste release. Customers should contact their board assembly site for stencil design recommendations. Refer to IPC-7525 for other stencil recommendations.
 - Customers should contact their board fabrication site for solder mask tolerances between and around signal pads.

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, modifications, enhancements, improvements, and other changes to its products and services at any time and to discontinue any product or service without notice. Customers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All products are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its hardware products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

TI assumes no liability for applications assistance or customer product design. Customers are responsible for their products and applications using TI components. To minimize the risks associated with customer products and applications, customers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any TI patent right, copyright, mask work right, or other TI intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information published by TI regarding third-party products or services does not constitute a license from TI to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. Reproduction of this information with alteration is an unfair and deceptive business practice. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

TI products are not authorized for use in safety-critical applications (such as life support) where a failure of the TI product would reasonably be expected to cause severe personal injury or death, unless officers of the parties have executed an agreement specifically governing such use. Buyers represent that they have all necessary expertise in the safety and regulatory ramifications of their applications, and acknowledge and agree that they are solely responsible for all legal, regulatory and safety-related requirements concerning their products and any use of TI products in such safety-critical applications, notwithstanding any applications-related information or support that may be provided by TI. Further, Buyers must fully indemnify TI and its representatives against any damages arising out of the use of TI products in such safety-critical applications.

TI products are neither designed nor intended for use in military/aerospace applications or environments unless the TI products are specifically designated by TI as military-grade or "enhanced plastic." Only products designated by TI as military-grade meet military specifications. Buyers acknowledge and agree that any such use of TI products which TI has not designated as military-grade is solely at the Buyer's risk, and that they are solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI products are neither designed nor intended for use in automotive applications or environments unless the specific TI products are designated by TI as compliant with ISO/TS 16949 requirements. Buyers acknowledge and agree that, if they use any non-designated products in automotive applications, TI will not be responsible for any failure to meet such requirements.
